SSC 120 Homework

For the two locations below, calculate the water balance. Graph the ETp (potential evapotranspiration) and P (precipitation) against months of the year. On each graph identify regions of deficit (D), recharge (R), surplus (S), and utilization (U) of soil water. Remember that the soil will store water up to its WHC (water holding capacity); any excess is surplus (surplus does not accumulate from one month to the next). During utilization of stored water, storage does not go below zero. Once ETp exceeds P, utilization begins.

Identify the probable soil moisture and temperature regimes from Soil Taxonomy. Remember to add 1 °C to the air temperature data to estimate MAST. Compare and discuss the potential for weathering and leaching at the two locations. What are the possible disadvantages of using long-term average precipitation data to predict leaching? Is a comparison between locations of only total precipitation sufficient to predict leaching and weathering potential? Explain.

SOIL A, WHC = 200 mm													
	J	F	M	A	M	J	J	Α	S	O	N	D	TOT
T °C	23	23	23	24	25	26	26	25	25	24	24	23
